ACOUSTIC DYNAMIC MODULUS OF STAPLE YARNS

Dana Křemenáková and Jiří Militký
Textile Faculty, TU Liberec Czech Republic, jiri.militky@tul.cz dana.kremenakova@tul.cz

Abstract: The acoustic or sonic pulse-propagation technique for the measurement of dynamic elastic modulus has the advantage of not being dependent on the sample cross-sectional characteristics. This technique also gives a direct measure of modulus rather than the indirect measure in the form of load versus extension. The sonic tests are relatively simple to apply and are nondestructive. The values of sonic modulus of fibrous structures are dependent on the orientation of components and packing density as well. The main aim of this work is to quantify the effect of yarn twist on the sonic modulus of staple yarns from synthetic and blended cotton type yarns. The results are compared with selected models of yarn twist influence on the mechanical properties of staple yarns. The correlation between yarn orientation factor defined by Pan and sonic modulus will be shown. The sonic modulus of yarns will be compared with tensile modulus.

1. INTRODUCTION

Studies of the fundamental dynamic mechanical properties of textile products are of prime importance if improvements to textile-processing equipment are to characterize textile structures. The acoustic or sonic pulse-propagation technique for the measurement of dynamic elastic modulus has the advantage of not being dependent on the sample cross-sectional characteristics. This technique also gives a direct measure of modulus rather than the indirect measure in the form of load versus extension. The sonic tests are relatively simple to apply and are nondestructive. The values of sonic modulus of fibrous structures are dependent on the orientation of components and packing density as well.

Let us assume that the staple yarn is composed of thin, elastic cylindrical rods with dynamic modulus $E$ and density $\rho$. The longitudinal sonic waves propagation is investigated. The rate of these waves spread $c$ is computed from well known relation $c = \sqrt{\frac{E}{\rho}}$. The acoustic dynamic modulus of yarn is much lower than acoustic dynamic modulus of fibers (corresponding multiplicative factor is in the wide range from 0.05 to 0.6). The decrease in acoustic dynamic modulus of yarns is influenced by the twist level mainly. From the acoustic dynamic modulus of yarns $E_y$ at some twist level $Z$ it is possible to calculate the approximate orientation factor $m$ in the acoustic dynamic modulus of yarns $E_y$ at some twist level $Z$ it is possible to calculate the approximate orientation factor. It is well known that twist has a crucial influence on the mechanical properties of short staple fiber yarns. The possibilities of prediction of twist influence on the fibers orientation in the staple polypropylene yarn are discussed in this work. The geometrical models based on the ideas of Gegauff [1], Pan [2, 3] and White [4] are compared with predicted mean orientation from measurements of yarns acoustic modulus and yarn initial tensile modulus. Increase of the polypropylene yarn twist level leads to the decrease of the yarn acoustic and initial tensile modulus and orientation of fibers as well.

The main structural factors which are significant for yarn modulus and strength prediction are packing density and orientation factor. These factors are influenced by raw material properties, technology of yarn production, yarn fineness and twist (yarn twist factor). It was shown that with the increasing twist coefficient the polypropylene yarn strength is reduced [7]. The yarn packing density is connected with friction between the fibers. Due to increasing of twist coefficient the packing density is increased as well to the limit value approximately 0.7 to 0.8. The increasing twist coefficient leads to the decreasing of orientation factor and therefore yarn strength is reduced. Yarn packing density was measured based cross-section
analysis. Orientation factor was measured based acoustic yarn and fiber bundle modulus and initial yarn and fiber bundle modulus. Results were compared with Gegaufl [2], White et. all [3] and Pan [4], [5] model.

2. THEORETICAL PART

Let the staple yarn is composed of thin, elastic cylindrical rods with dynamic modulus $E$ and density $\rho$. Let the longitudinal sonic waves propagation is investigated. The rate of these waves spread $c$ is computed from well known relation [5]

$$c = \sqrt{(E / \rho)}$$

(1)

The acoustic dynamic modulus of yarns is much lower than acoustic dynamic modulus of fibers (multiple factor is in the wide range from 0.05 to 0.6). Acoustic dynamic modulus of yarns decrease is influenced by the twist level mainly. In 1907 Gegauff [1] proposed a simple analysis to correlate the twist angle of yarn $\beta$ with the yarn modulus $E_y$. Based on yarn helical model the tangents of surface fiber helix angle $\beta$ is directly connected with number of twists $Z$ and yarn diameter $D$ i.e.

$$\tan \beta = \pi DZ$$

(2)

Yarn acoustic modulus $E_y$ at the twist level $Z$ is then function of fiber modulus $E_f$

$$E_y = E_f \cos^2 \beta \approx E_f \left(1 + \pi DZ \right)^2$$

(3)

For definition of real yarn diameter it is possible to define yarn packing density $\mu$. Packing density is generally defined as ratio between fiber volume $V_f$ and whole yarn volume $V_y$, as it is shown below

$$\mu = \frac{V_f}{V_y} = \frac{4T}{\pi D^2 \rho}$$

(4)

where $T$ is yarn fineness, $D$ is yarn diameter and $\rho$ is fiber density. Packing density $\mu$ can be calculate by using the following relationship [6]

$$\left(\frac{\mu}{\mu_m}\right)^{\frac{3}{2}} = \frac{M \sqrt{\pi}}{2 \mu_m^{\frac{3}{2}} \sqrt{\rho}} \left(Z T^{\frac{1}{4}} \right)^2$$

(5)

where $M$ is the material and technology parameter and $\mu_m$ is the limit packing density. A suitable value of parameter $M$ for polypropylene yarns was found in [7].

White et. all [4] proposed more complex analysis based on the continuum mechanics. Their final equation has the form

$$E_y = E_f \left(\frac{1}{4} + \frac{9F}{4} + \frac{3F}{(1-F)} \ln \sqrt{F}\right)$$

(6)
where $F = \cos^2 \beta_D$. Pan [2, 3] derived orientation factor $\eta_\beta$ as a function of surface fiber helix angle $\beta_D$ and yarn Poisson ratio $\eta$

$$\eta_\beta = \frac{2\beta_D(1-\eta)+(1+\eta)\sin 2\beta_D}{4\beta_D}$$

(7)

Poisson ratio $\eta$ has the form [2]

$$\eta = \frac{\sin^5 \beta_D}{2(1-\cos^3 \beta_D)\left(\frac{1}{2}\beta_D - \frac{1}{4}\sin 2\beta_D\right)}$$

(8)

From the acoustic dynamic modulus of yarns $E_y$ at some twist level $Z$ it is possible to calculate the approximate orientation factor $\eta_\beta$ from simple relation

$$\eta_\beta = \frac{E_y}{E_b}$$

(9)

where $E_b$ is the acoustic dynamic modulus of yarns without twist (i.e. fibrous bundle). The $E_b$ is in fact replacing the fiber modulus in eqn (3) and (6). The eqn (9) can be used for prediction of orientation from yarn initial tensile modulus as well.

3. EXPERIMENTAL PART

The thirteen compact polypropylene yarns of the same fineness $T = 25$ tex with different twist were spun. Instead of twist level $Z$ the Phrix's twist coefficient $\alpha$ [m$^{-1}$ ktex$^{2/3}$] was computed

$$\alpha = Z \cdot T^{2/3}$$

(10)

Properties of polypropylene fibers are summarized in the Table 1. Yarns were produced in the pilot plant conditions so as to achieve the smallest and greatest possible twist, twist factor was from 30 to 98 [m$^{-1}$ ktex$^{2/3}$]. The yarns sonic velocity was measured on the apparatus Dynamic Modulus Tester (Lawson Hemphill) with piezoelectric crystal transducer. The initial tensile modulus of yarns was calculated from smoothed stress strain curves measured on the tensile testing machine under standard conditions. The smoothing was realized by using of optimal cubic smoothing splines [8]. The limit packing density $\mu_m = 0.7$ and optimal value of parameter $M = 0.0919$ [m] for polypropylene yarns were used.

4. RESULTS AND DISCUSSION

The acoustic dynamic modulus of yarns without twist $E_d$ was calculated from linear dependence of yarn sonic velocity on the twist coefficient $\alpha$ (extrapolation to the $\alpha = 0$). This dependence is shown in fig. 1.

**Figure 1:** Sonic velocity as function of yarn twist coefficient

The linear dependence of sonic velocity on the twist coefficient is fairly good with squared correlation coefficient $R^2 = 0.77$. The extrapolated sonic velocity of yarns without twist is 1.898 km/s. Corresponding acoustic dynamic modulus of yarns without twist $E_d$ calculated from eqn. (1) is equal to 3.367 GPa. The dependence of yarn initial tensile modulus on the twist coefficient $\alpha$ is shown in fig. 2. The linearity of this dependence is very good with squared correlation coefficient $R^2 = 0.918$. Extrapolated initial tensile modulus of yarns without twist is equal to 1.624 GPa. It is clear than the static modulus is lower in comparison with sonic (dynamic) modulus.

**Figure 2:** Initial tensile modulus as function of yarn twist coefficient
The experimental orientation factors computed from sonic modulus and initial tensile modulus are shown in the fig. 3. The lines corresponding to the orientation factor calculated from Gegauff, Pan and White models are shown as well.

**5. CONCLUSION**

The influence of twist factor on the orientation of polypropylene staple yarn was studied. With the increasing of twist coefficient yarn acoustic modulus and yarn initial modulus is decreasing. The linear dependence of POP yarn acoustic modulus and POP yarn initial modulus on the twist coefficient were found. The acoustic dynamic modulus and initial modulus of yarns without twist were calculated from these linear dependences. Experimental orientation factors at various twist level were calculated as ratio between acoustic (initial) yarn modulus at some level and acoustic (initial) modulus of yarn without twist. It was found that for prediction of orientation factor from sonic modulus is the best the Pan model (see eqn.(7)) and for prediction of orientation factor from initial tensile modulus is the best the White model (see eqn.(6). The Pan model is suitable for prediction of yarn strength.
